I. Introduction

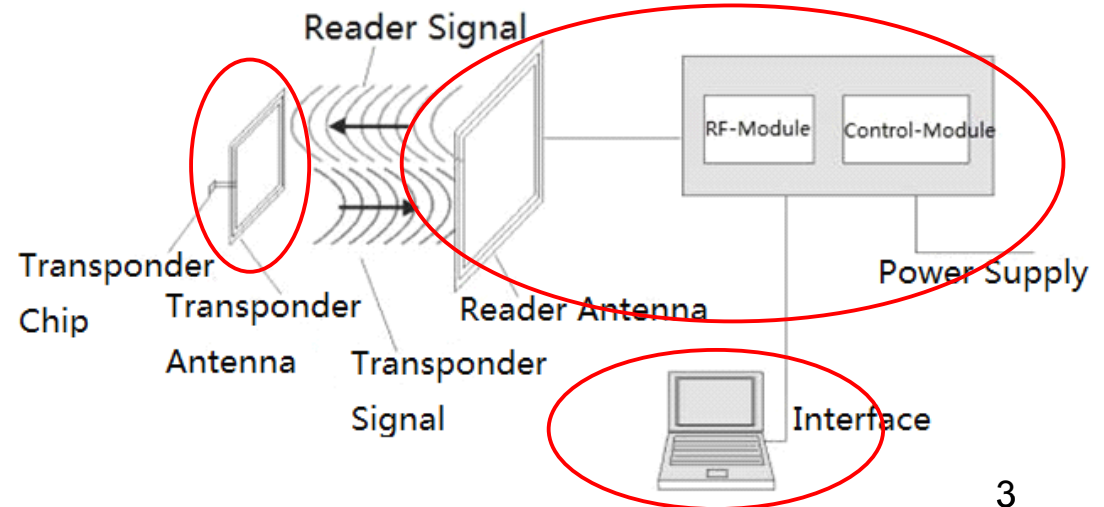

❖ RFID: an enabler of IoT

Being attached almost to everything making it intelligent. If all objects were equipped with RFID tags, they could be identified by the PC.

RFID tag, or transponder

RFID reader, or transceiver

back-end database

I. Introduction

❖ Low-cost RFID tags:

Lacking resources to perform true cryptographic operations.

❖ Research challenges:

The communication channel between the tag and the reader is *insecure*. Hence, the low security performance may result in leakage of personal information.

II. Security Requirements for low-cost Tags

❖ Confidentiality

All of the information in the protocol is **securely transmitted**.

❖ Indistinguishability

The sent information from the tag or the reader should not be **different** from the sent information of other tags.

❖ Forward Security

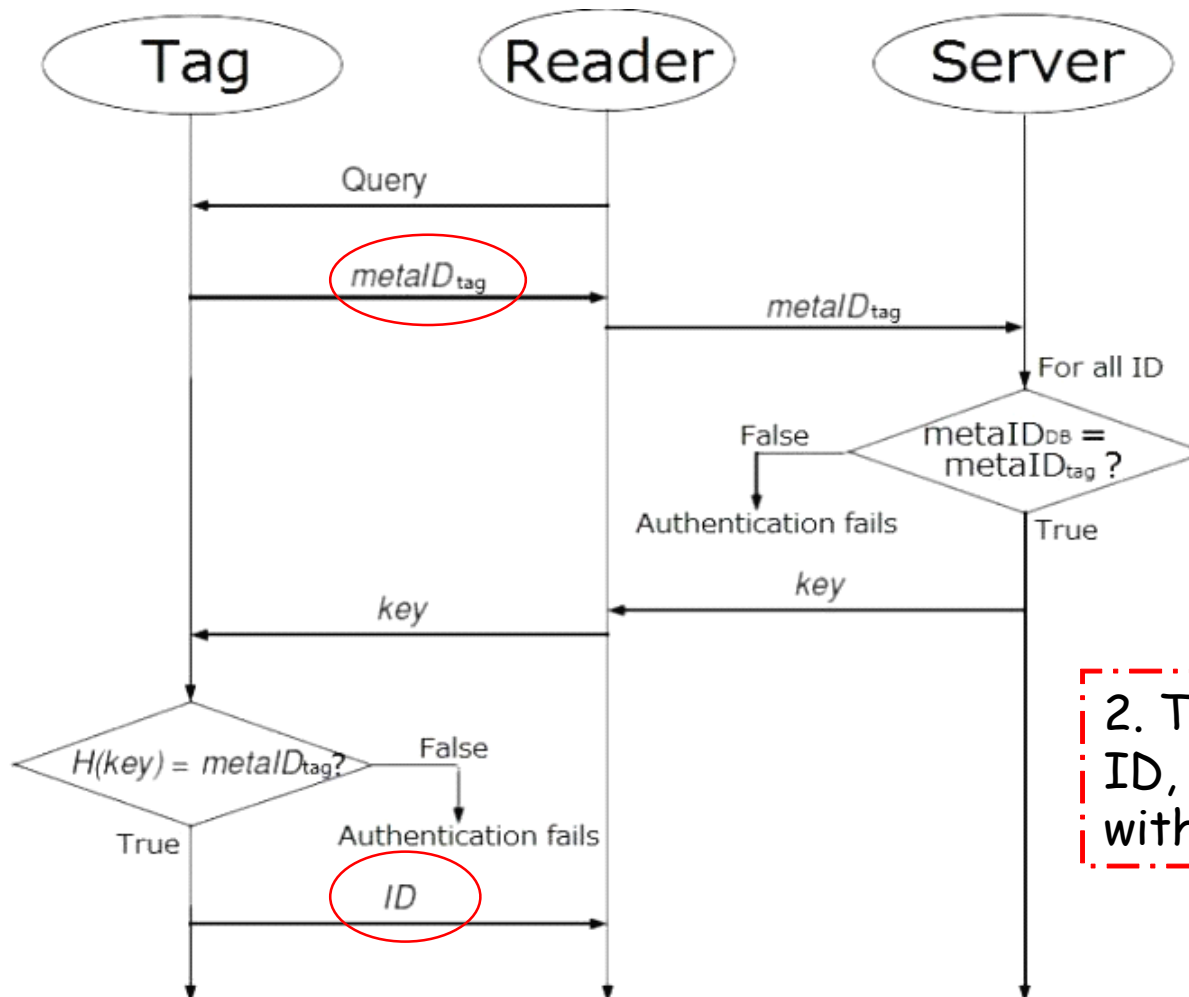

The **previously** sent information **cannot be tracked** using the **present** information of the tag.

❖ Mutual Authentication

Unlike the more common RFID authentication protocols where **only one side** (either the reader or the tag) authenticate the other.

III. Related work

❖ Hash Lock protocol

Challenge

1. The $metaID_{tag}$ keeps same in each authentication process.

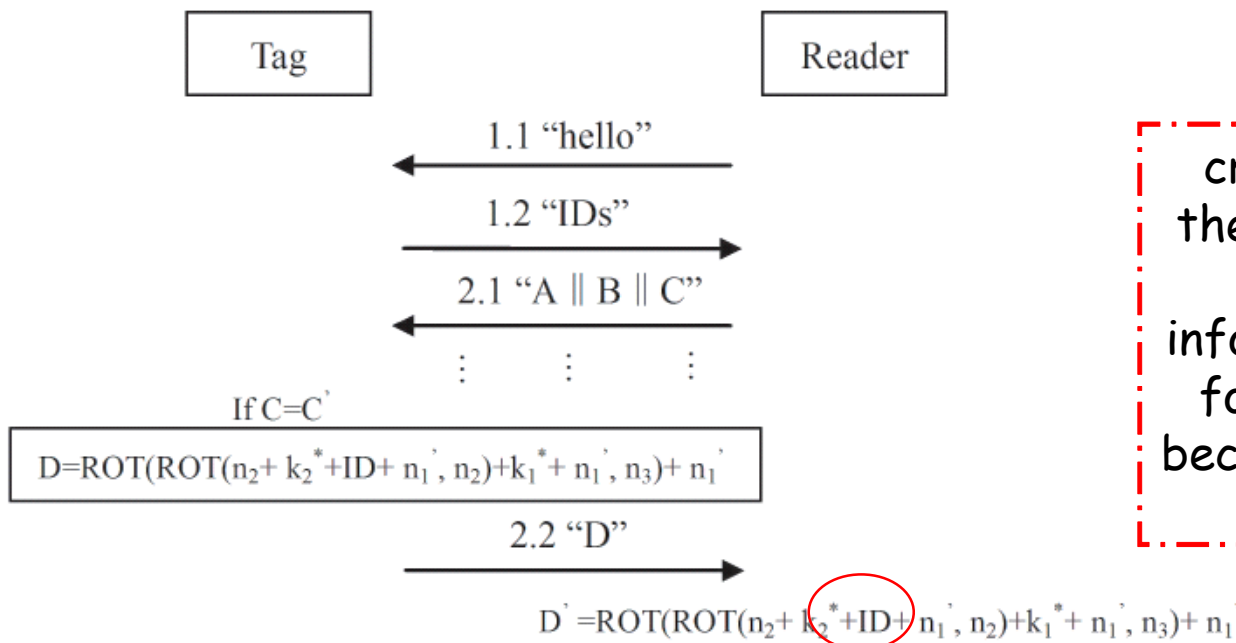

2. The tag's identifier, ID, is directly sent without any encryption.

III. Related work

❖ Gossamer Protocol

The protocol is made up of three stages: (1) tag identification, (2) mutual authentication, and (3) index pseudonym (IDS) and key updating.

Challenge

cryptanalysis shows that the attack is possible when the tag transmits information D to the reader for authenticating itself, because it contains the tag's information ID,

III. Related work

❖ security issues of the existing protocols

	Hash Lock	Randomized Lock	one time password	Gossamer
Confidentiality	○	○	○	△
Forward security	×	×	×	○
Mutual authentication	×	×	○	○
Eavesdropping	×	×	△	△
Track attacking prevent	×	○	○	○

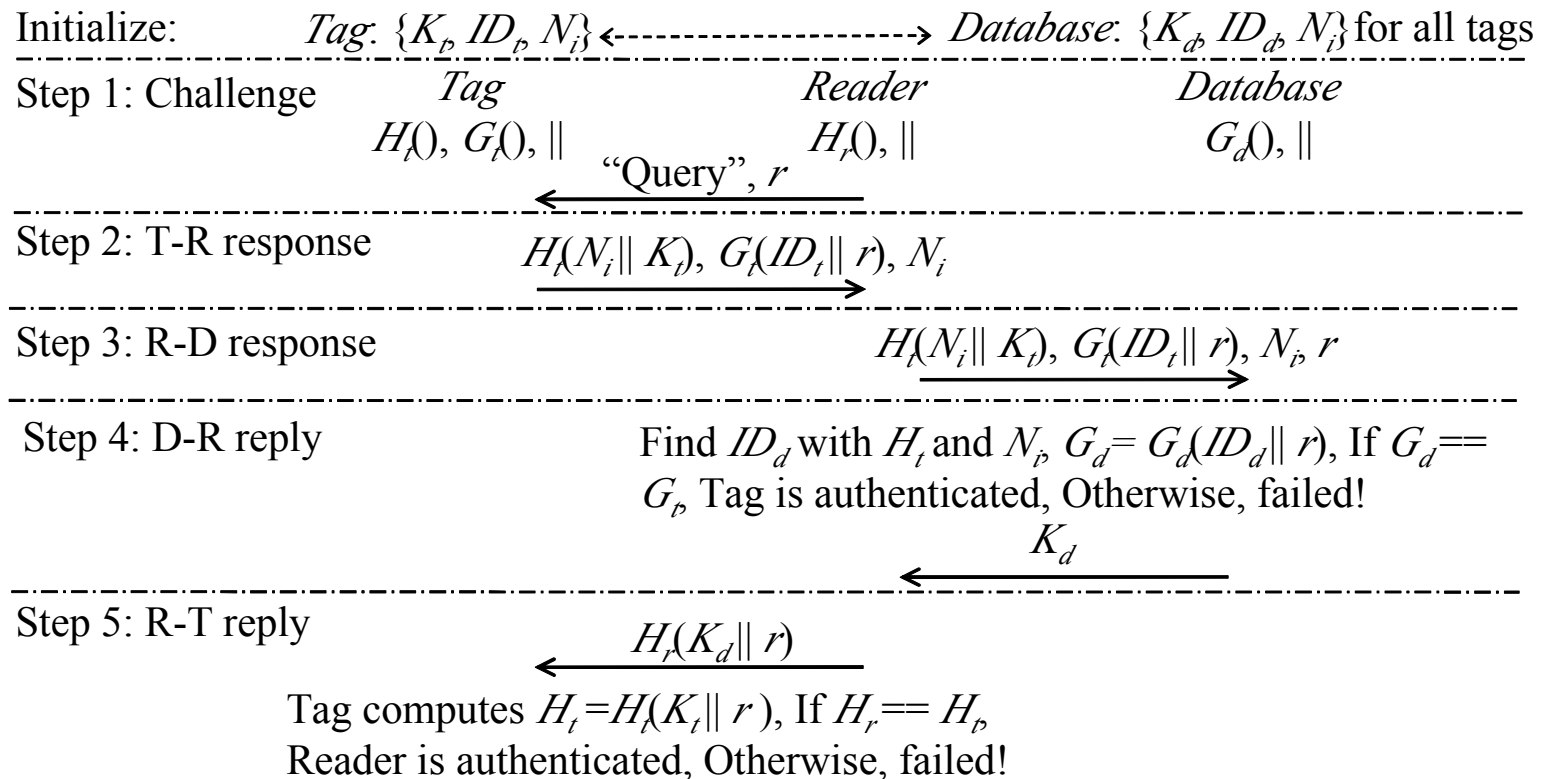

❖ A new protocol based on the ideas of hash locker and mutual authentication mechanism is proposed.

IV. The proposed protocol

❖ Assumptions and Notations

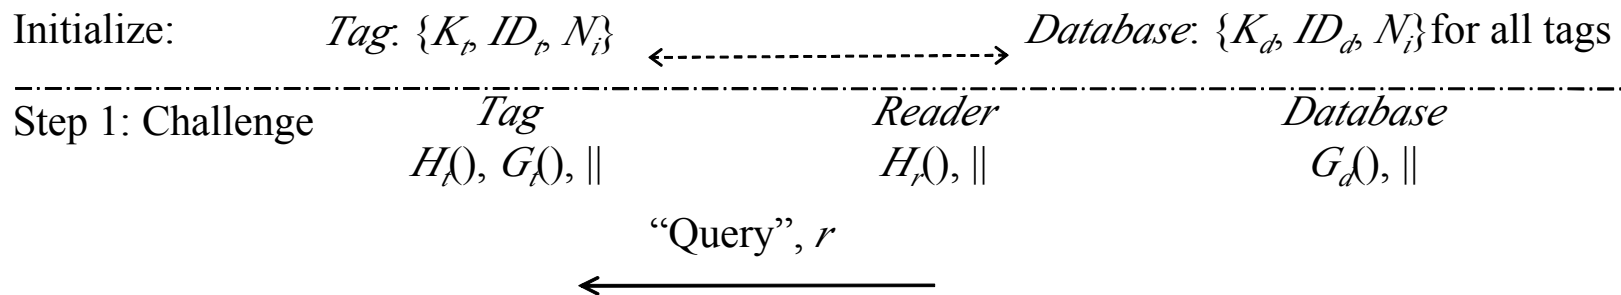

1. A tag is passive and has a rewritable memory such as EEPROM with reasonable size.
2. The communication channel between the reader and the back-end database is secure.
3. The cryptographic hash function in the protocol requires security of preimage resistance, 2nd-preimage resistance, collision avoidance.

IV. The proposed protocol

T Tag, or transponder	Kt The secret key stored in the tag
R Reader, or transceiver	Kd The secret key stored in the database
D Database	r Random number generated
IDt Identification value stored in the tag	Link operation
IDd Identification value stored in the database	
Ni The ith nickname, $i=1, \dots, n$. n is the number of nicknames stored in the tag	

IV. The proposed protocol

Initial setup:

Each tag stores its identifier, ID_t , secret key, K_t , and several nicknames, N_i . And shared within the back-end database.

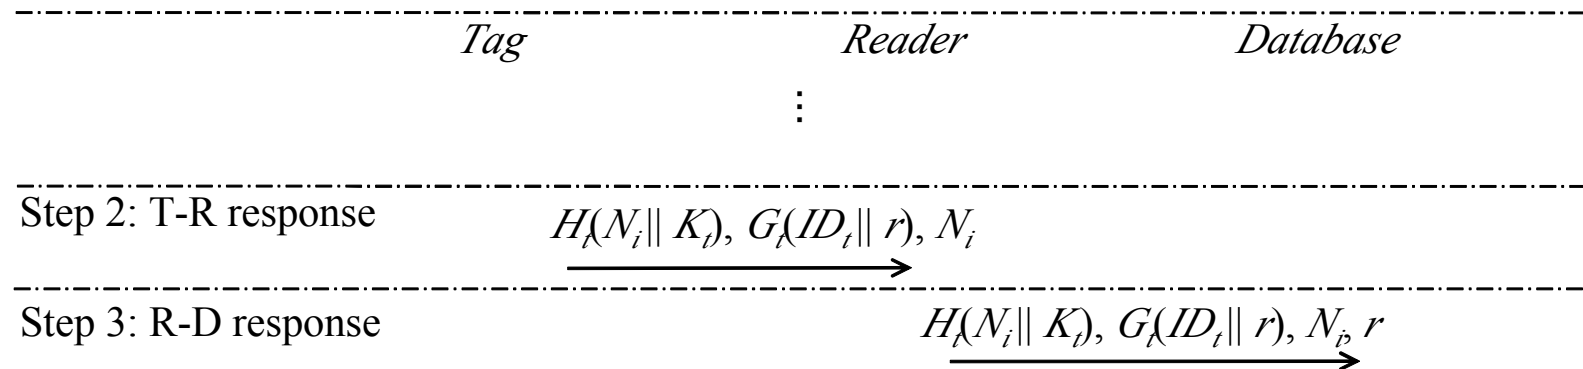

Each tag has 2 hash functions, $H_t()$ and $G_t()$, and link operation. And the reader has a random number generator.

Step 1 (Challenge):

The reader generates a fresh random nonce, r , and sends it with query to the tag.

IV. The proposed protocol

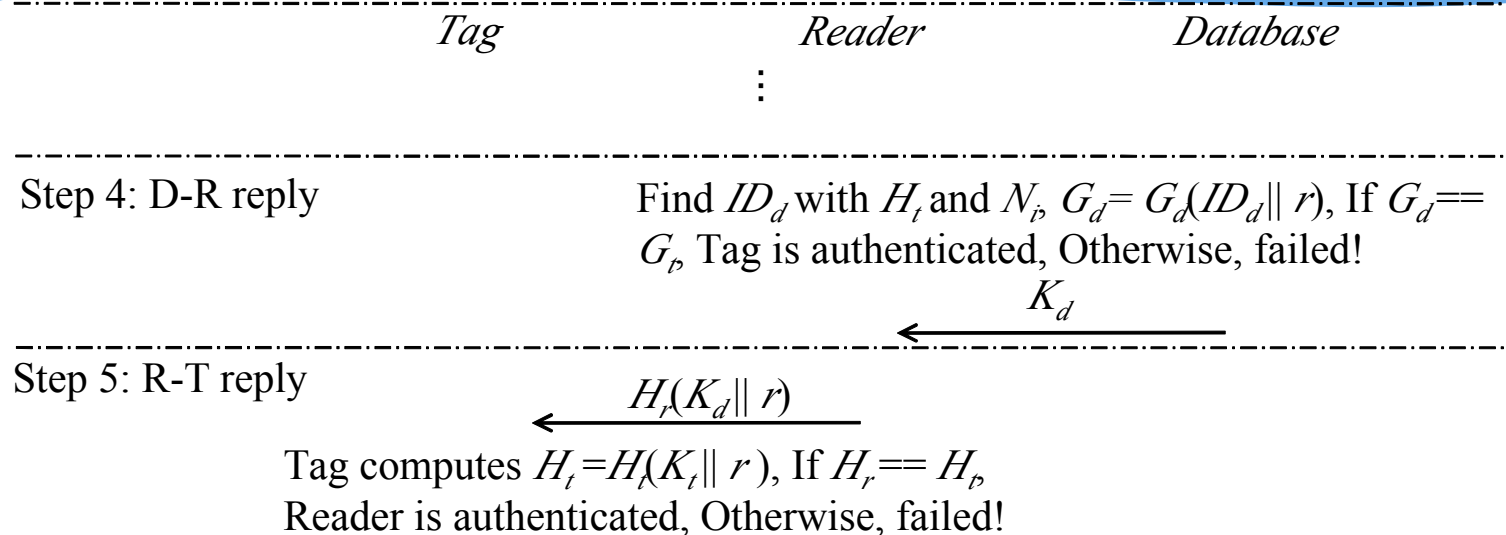

Step 2 (T-R response)

After being queried, the 2 hash values, H_λ and G_λ , are calculated and sent to the reader with the picked nickname in this step.

Step 3 (R-D response)

The received information H_λ , G_λ , N_i and r , is sent to the database to find the corresponding secret key, K_d , stored in the database.

IV. The proposed protocol

Step 4 (D-R reply)

The database will look for ID_d due to the received N_i and the initially-stored hash values. The database computes the hash value G_d and compares with the received G_t ; if G_d equals G_t , the tag is authenticated by the reader.

If succeeds, K_d is sent to the reader.

IV. The proposed protocol

Step 5 (R-T reply)

After receiving K_d , the reader computes the hash value, H_r and then sends to the tag. On the tag side, it computes H_t and compares with H_r . If H_t equals H_r , the reader is successfully authenticated; Otherwise the protocol fails to execute.

V. Analyses

❖ Security Analyses

Protocol	HL	RHL	Gossamer	Proposed
Confidentiality	OK	OK	moderate	OK
Indistinguishability	ng	ng	OK	OK
Forward security	ng	ng	OK	OK
Mutual authentication	ng	ng	OK	OK
Eavesdropping attack prevent	ng	ng	moderate	OK
Spoofing attack prevent	ng	ng	OK	OK
Replay attack prevent	ng	ng	OK	OK
Track attacking prevent	ng	OK	OK	OK

V. Analyses

❖ Performance analyses

Protocol		HL	RHL	Gossamer	Proposed
No. of hash	Tag	1	2	–	3
	Reader	–	–	–	1
	DB	–	N	–	N
No. of RNG	Tag	–	1	3	1
	Reader	–	–	–	1
	DB	–	–	–	–
No. of ROT	Tag	–	–	8	–
	Reader	–	–	10	–
	DB	–	–	12	–
No. of auth steps		6	5	5	5
Required memory	Tag	$2L$	L	$7L$	$2L + nL$
	DB	$4LN$	LN	$4LN$	$(2L + nL)N$

VI. Simulation

❖ Pseudo-code in tag(1)

```
enum sysState = { s_ini, s_check, s_pass, s_fail };
```

```
int AutoRun_Authentication ( )
```

```
{
```

```
    char * s, *Hr, * r, *Ni;
```

```
    int i;
```

```
    sysState = s_ini;
```

```
    waitQuery(&r);
```

```
    i = Random(1,n);
```

```
    switch(i)
```

```
    {
```

```
        case 1: Ni = N1; break;
```

```
        case 2: Ni = N2; break;
```

```
        ⋮
```

```
        case n: Ni = Nn; break;
```

```
        default: Ni = N1;
```

```
    }
```

// Initialize

VI. Simulation

❖ Pseudo-code in tag(1)

```
enum sysState = { s_ini, s_check, s_pass, s_fail };
```

```
int AutoRun_Authentication ( )  
{
```

```
    char * s, *Hr, * r, *Ni;
```

```
    int i;
```

```
    sysState = s_ini;
```

```
    waitQuery(&r);
```

```
    i = Random(1,n);
```

```
    switch(i)
```

```
    {
```

```
        case 1: Ni = N1; break;
```

```
        case 2: Ni = N2; break;
```

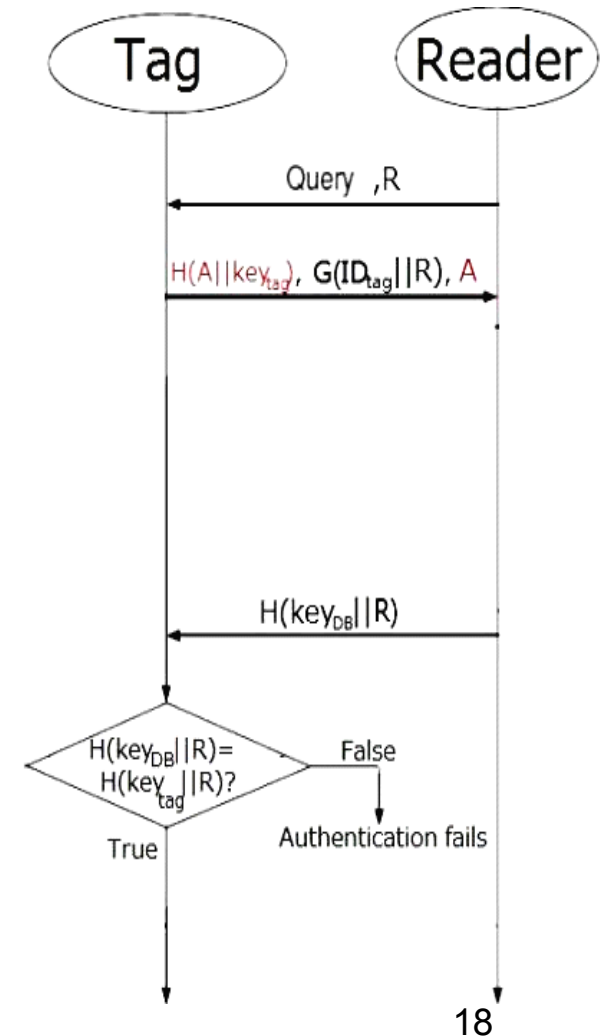

```
        ...
```

```
        case n: Ni = Nn; break;
```

```
        default: Ni = N1;
```

```
    }
```

// pick up
nickname

VI. Simulation

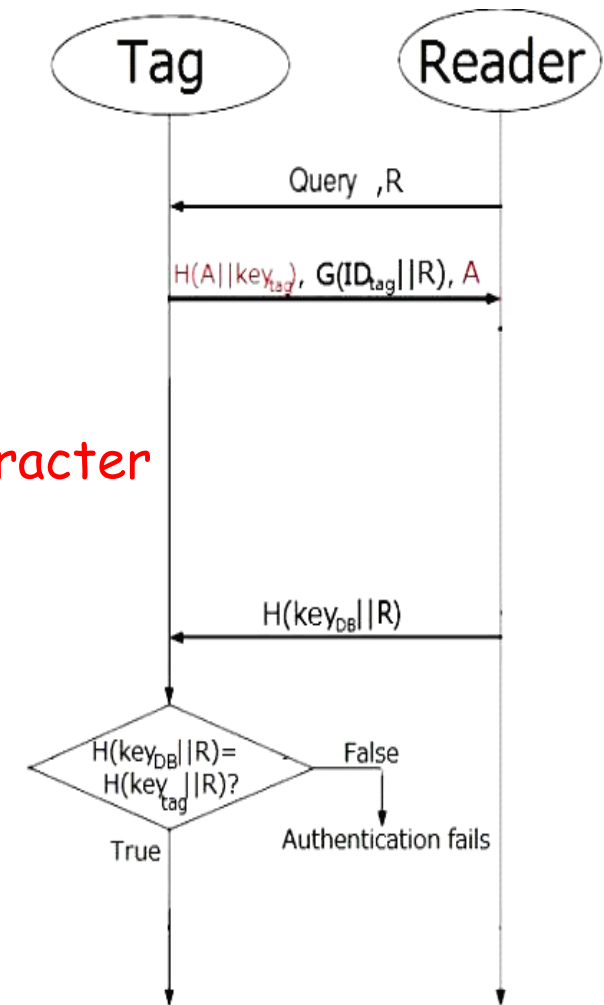

❖ Pseudo-code in tag(2)

```
s = connectchar( H( Ni || Kt ), G( IDt || r ) );  
s = connectchar( s , Ni );  
send(s);
```

```
sysState = s_check;  
waitHashString( & Hr );  
s = comparechar( Ht( Ni || Kt ), Hr );  
if ( s == 0 ) sysState = s_pass  
else sysState = s_fail;
```

```
}
```

// connect character
& send

VI. Simulation

❖ Pseudo-code in tag(2)

```
s = connectchar( H( Ni || Kt ), G( IDt || r ) );  
s = connectchar( s , Ni );  
send(s);
```

```
sysState = s_check;  
waitHashString( & Hr );
```

```
s = comparechar( Ht( Ni || Kt ), Hr );  
if ( s == 0 ) sysState = s_pass  
else sysState = s_fail;
```

```
}
```

// comparechar -> authenticate

VI. Simulation

❖ Pseudo-code in reader

```
void Query( char* d_Ht ,d_ Gt , d_Ni , d_r )  
{  
    char* Ht, Gt, Ni; // buffer  
    r = Random(1,n);  
    send (r );  
    waitResult( &Ht, &Gt, &Ni );  
    d_Ht = Ht;  
    d_ Gt = Gt;  
    d_Ni = Ni;  
    d_r = r;  
}
```

```
Void AuthToCard( char* Kd )  
{  
    send (Hr(Kd || r));  
}
```

// waiting
result

VI. Simulation

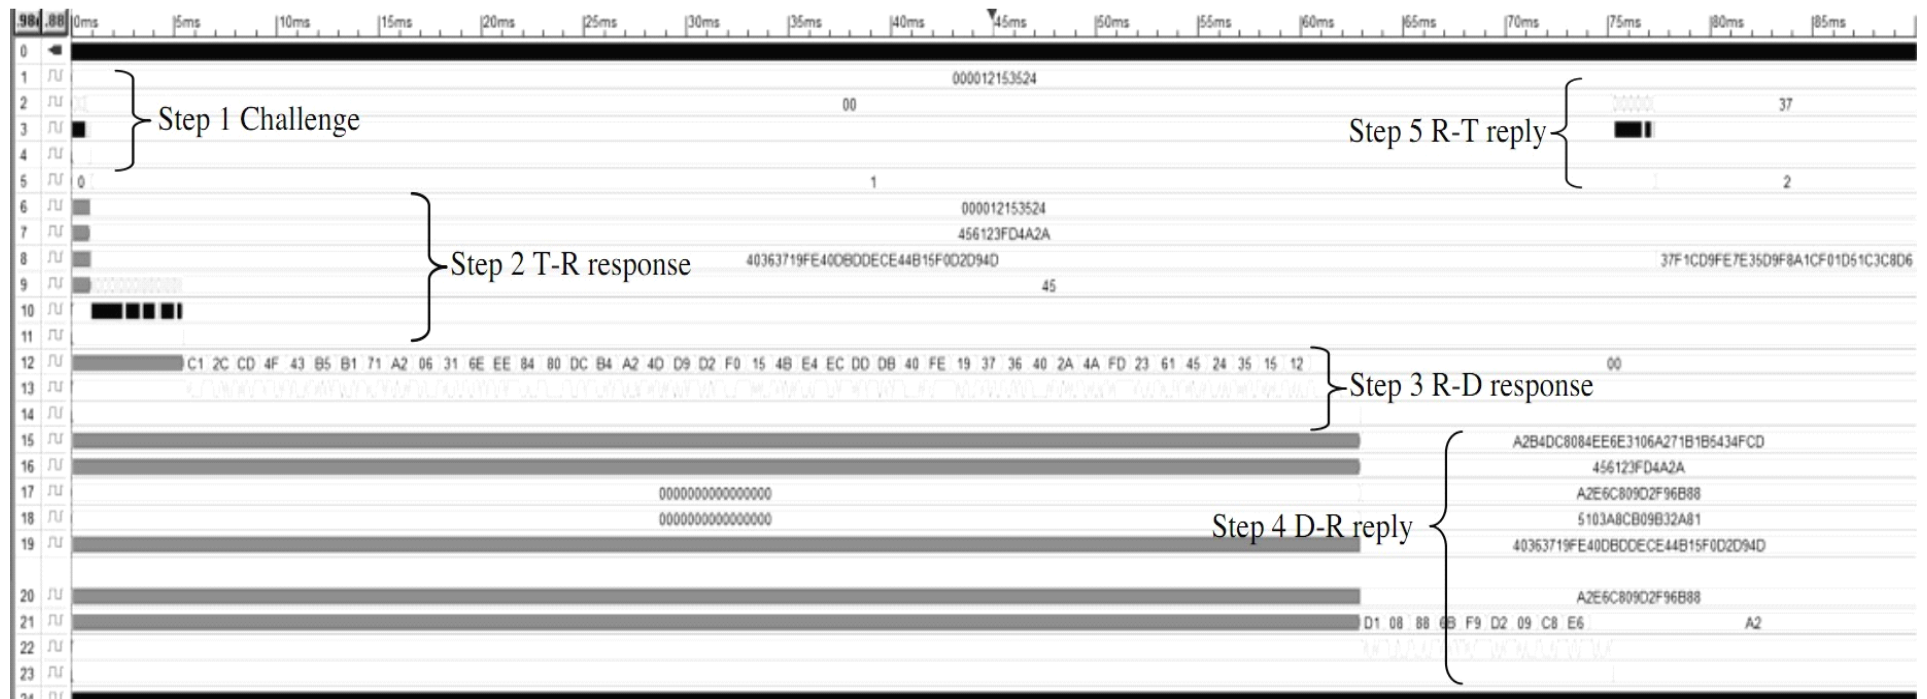

❖ Simulation environment

- OS: Windows
- Software: TestBencher Pro
- Language: VERILOG

❖ Processing time

- The proposed: 77.33ms
- Gossamer: 120.4ms

Same of (rate of bottom layer, database, operation system)

Conclusions

- ❖ A new mutual authentication protocol based on the **hash function** and the **nicknames** is proposed and the **efficiency** of the proposal has been verified in the **simulation**.
- ❖ The **security** analyses and **performance** analyses show that the proposed protocol is **secure against** several types of attacks.
- ❖ The **randomly-chosen nickname** is utilized in authentication, during which the **security level** is assured due to the **fuzziness** of the **picked nicknames** and the usage of **hash encryption**.
- ❖ In conclusion, the proposed protocol has **great potentials** for low-cost RFID tags in the IoT system.

Thank You !
