- USN Applications
- USN Problem Domains
- USN Service Requirements
- USN Technical Issues
- USN Technology Layer Model
- Non-IP USN Networking Solutions
- IP-USN Networking Solutions
- Conclusions

## ■ WSN vs. USN

## ■ WSN

- Definition: a mesh network of small sensor nodes communicating among themselves using RF communication, and deployed in large scale (from tens to thousands) to sense the physical world. (Source: WIKIPEDIA)
- Physical components: small MCU, limited memory, sensors (including specific conditioning circuitry), communication device (usually radio transceivers), battery, etc.
- Characteristics: small-scale sensor nodes, limited power they can harvest or store, harsh environmental conditions, node failures, mobility of nodes, dynamic network topology, communication failures, heterogeneity of nodes, large scale of deployment, and unattended operation

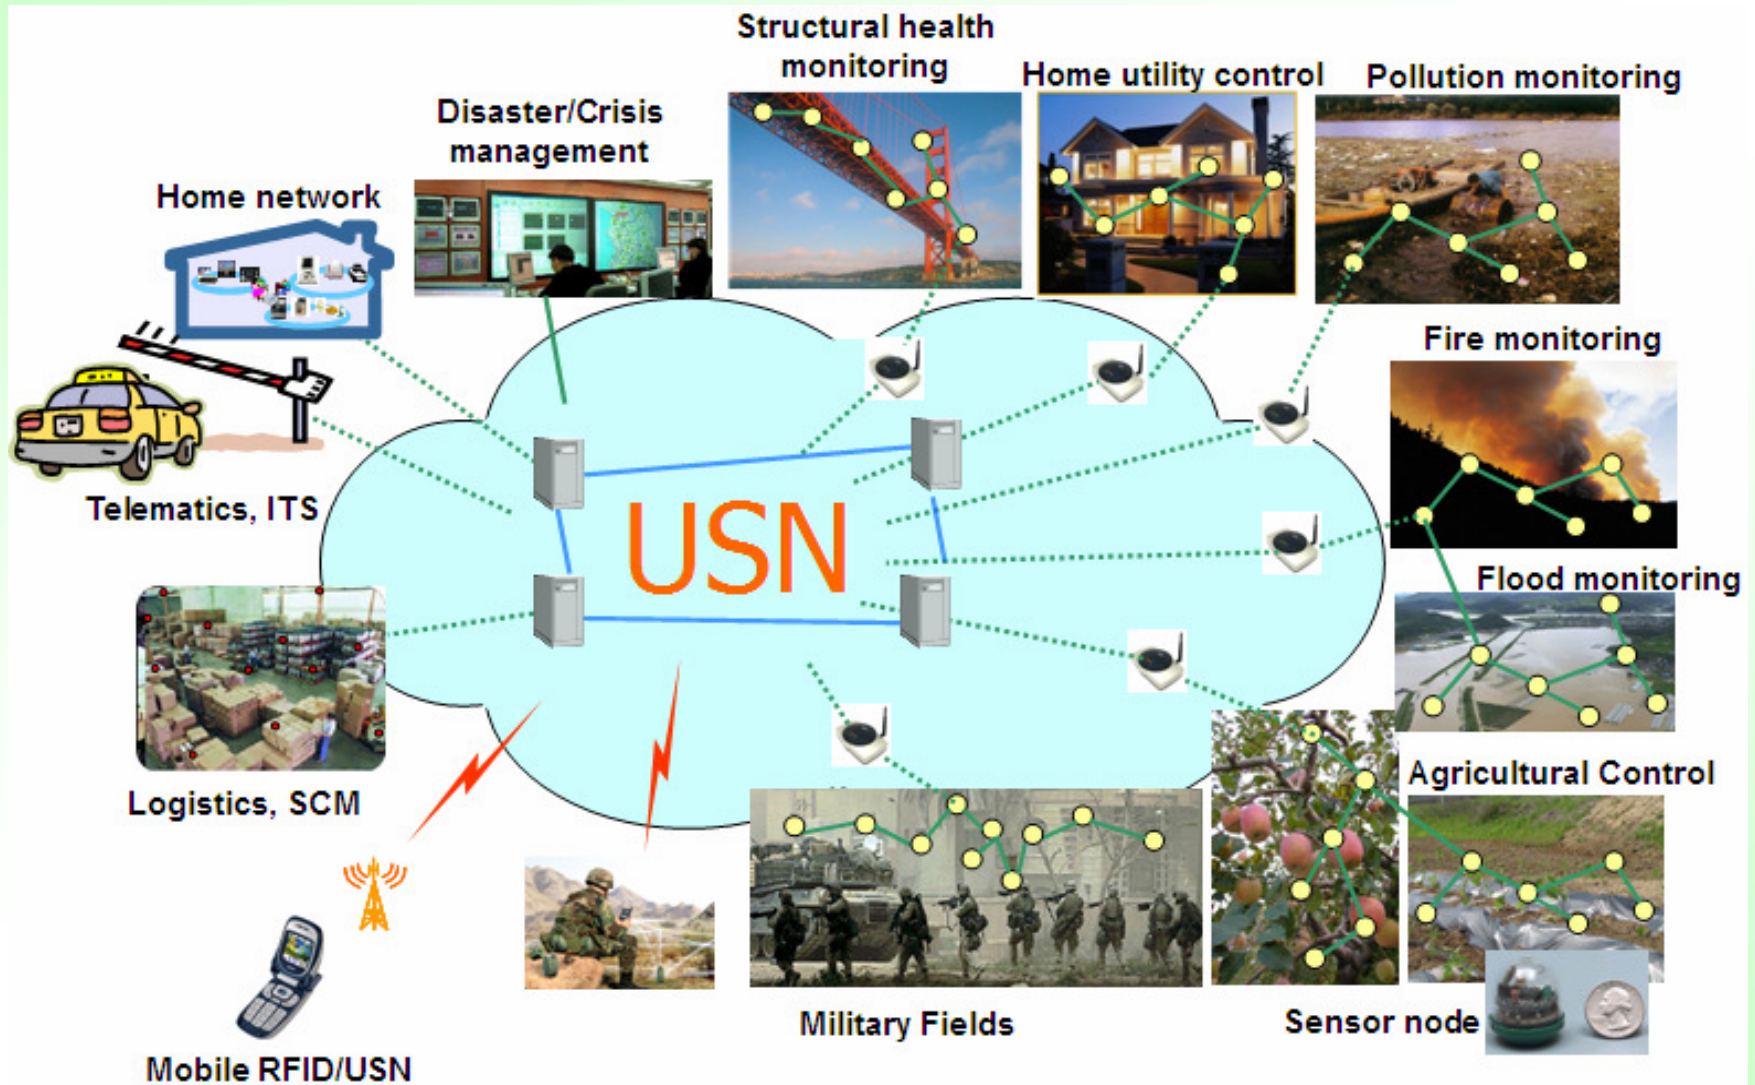

## ■ USN

- Not a simple network but an intelligent information infrastructure of advanced e-Life society, which means it is not a network technology term but a service infrastructure term
- It delivers user-oriented information and knowledge services to anyone at anywhere and anytime where the information and knowledge is developed by using context awareness with detecting, storing, processing and integrating situational and environmental information gathered from sensor tags and/or sensor nodes affixed to anything.
- Two viewpoints
  - Network installation view
  - Application/service view
- USN deals with both viewpoints.

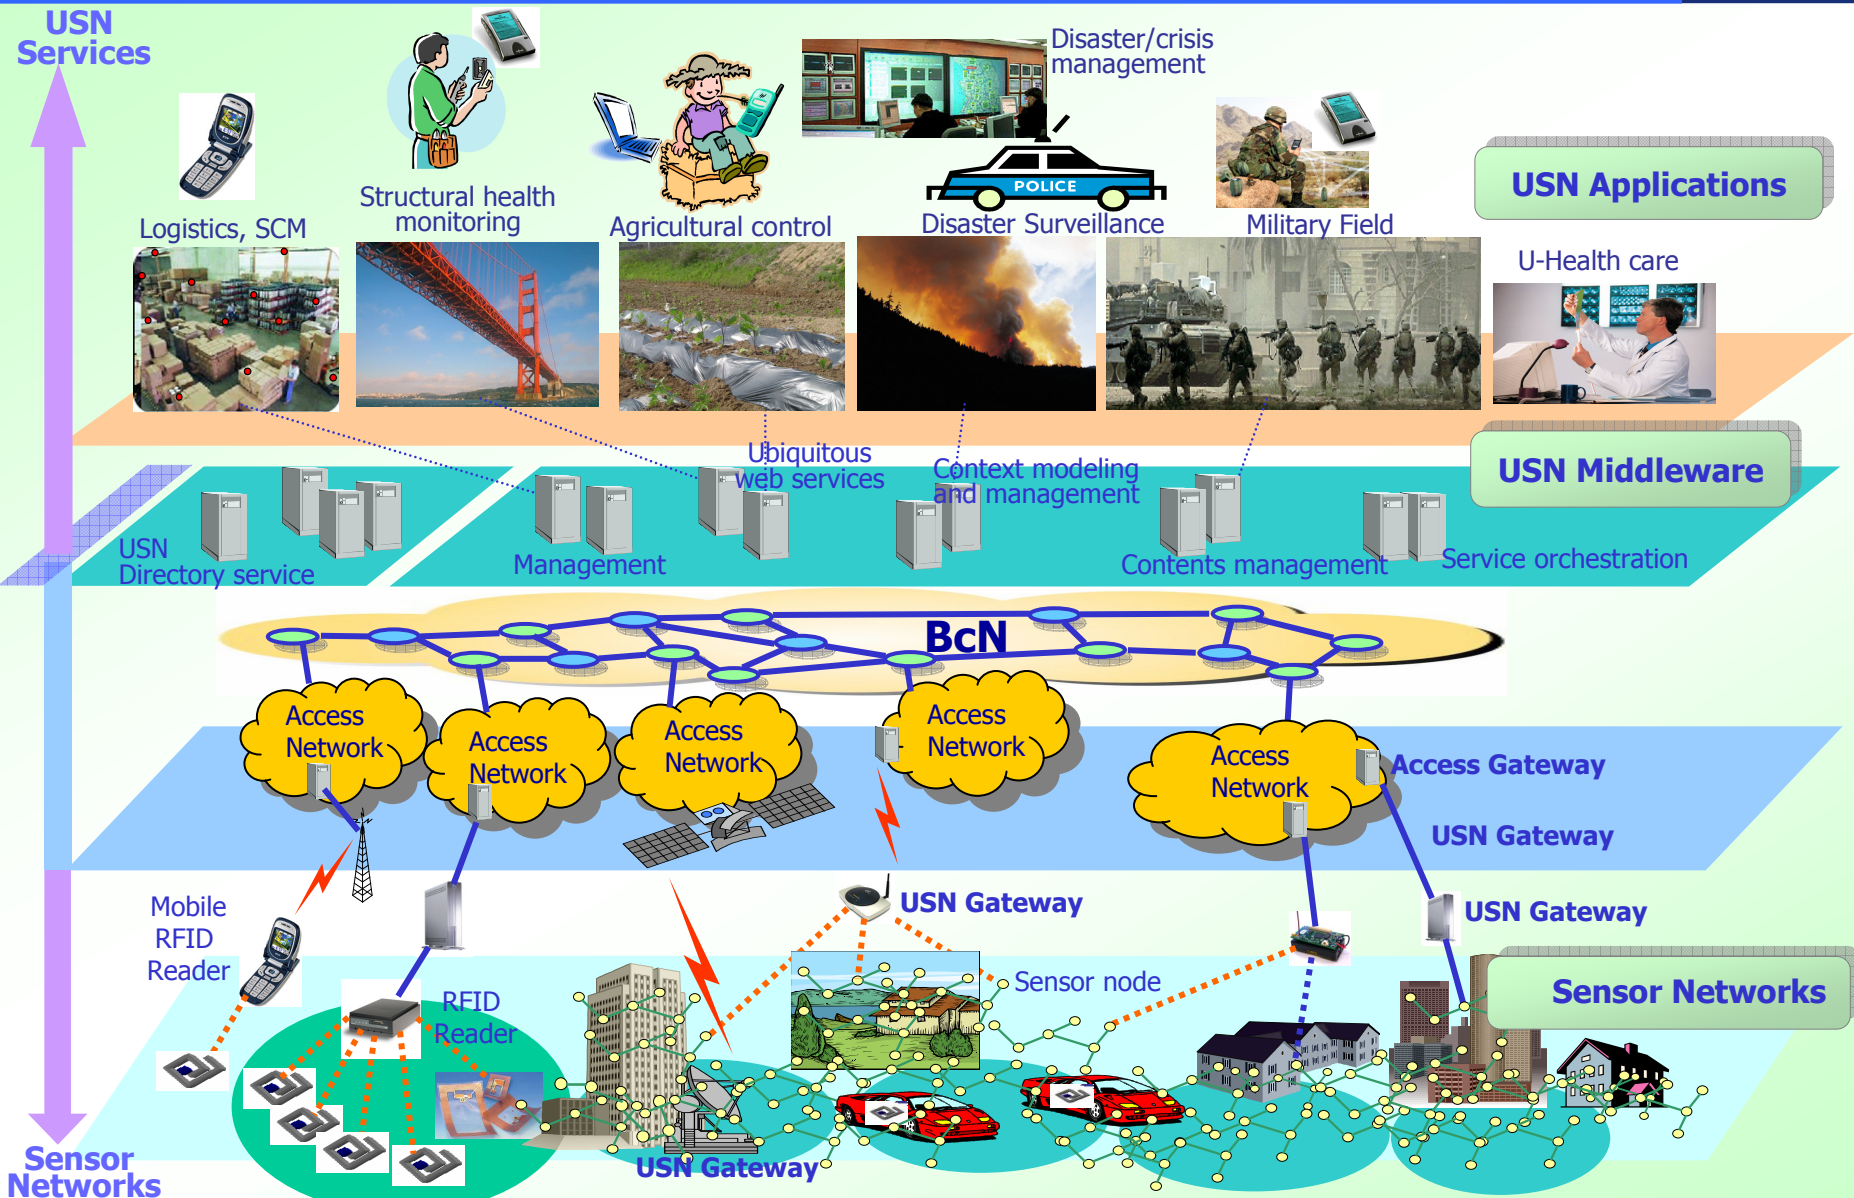

## ■ WSN vs. USN

- WSN is a networking technology term and focuses on sensor node networking and node system development.
- USN is not a technology term but a user- and service-perspective term which shall cover lower-layer and higher-layer issues including PHY/MAC, networking aspects, application protocol and language issues, middleware functions, various management topics, context awareness services, and a variety of applications and services.

# USN Applications

# USN Problem Domains

- Sensor node is not general purpose device.
  - It has a specific purpose and limited usage.
  - Many application programs are not installed.
  - Application programs are not changed frequently.
  - Sensor-dedicated applications are installed.
  - Applications installed keep used for a long time.
- Each application has unique service and functionality requirements.
  - Fire monitoring
  - Intrusion detection
  - Military use cases
  - Weather information gathering
  - Body condition monitoring
  - Pollution monitoring

# USN Service Requirements (2/7)

## Virtual Market Characteristics

	Border guard	Weather information gathering	Bridge condition monitoring	Mountain fire monitoring	Health care	Home care
Heavy data volume						
Light data volume						
Mobile node						
Stationary node						
Mobile network						
Stationary network						
Battery						
Power-line support						
Streaming data						
Periodic data						
Event-driven data						
Wire-line comm.						
Wireless comm.						
Many nodes						
Several nodes						
In-door						
Out-door						

## Virtual Market Characteristics

### ■ Design spaces of WSN by ETH Zurich

- Deployment
- Mobility
- Cost, size, resources and energy
- Heterogeneity
- Communication modality
- Infrastructure
- Network topology
- Coverage
- Connectivity
- Network size
- Lifetime
- QoS requirements

- Functional requirements and design specification are possible to be limited for a specific use case.
  - Limited design specification can enable various technology solutions.
  - Even sensor-built-in RFID tag may be useful enough.
- Vender's proprietary solutions could be successful in limited purpose and various application environment.
  - A specific solution which meets customer requirements can be competitive against a general purpose solution.
  - Even a simple function can make customers happy even though many functions are not provided.

- Cost effectiveness is a vital factor for success because USN may handle a huge number of sensor nodes.
  - Cost effective design for S/W and H/W is very important technology and engineering target.
  - Maintenance and management cost should be considered.
    - Labor cost for sensor node and network maintenance/management
    - Labor cost for battery change
    - Battery cost
    - Troubleshooting cost
    - Opportunity cost by service failures; and so on
  - Maintenance/management cost >> installation cost

- Lots of applications have a formatted and tiny data size.
  - Size of raw data can be decreased by a sophisticated data structure design. Mapping or scaling can be a solution to do that.
  - A single message can be enough for data transmission. (Ex. Default payload size of TinyOS is 29 bytes.)
- USN isn't be established by personal interests but established by business purposes as well as turn-key basis.
  - So, non-standard solution is possible because the turn-key basis can enable a solution package with non-standard but well-functioning technology solutions.
- Sensor node shouldn't be open to the public for consumers' access due to security and management reasons.
  - Public information service is provided via a backend application system, not direct communication with sensor nodes.

- Wireless networking is not the only networking solution.
  - Wire-line networking can be more effective in some cases or could be mandatory.
  - But, wireless must be the promising solution for sensor networking.
- Sensor node and network is installed by installation experts and managed by management experts.
  - Consumers don't buy, install and manage sensor nodes and networks while they do so for television.
  - This property can enable automatic operation requirement to be excluded from functional requirements.
- Usually performance and throughput are not that important. But, availability and survivability are more important.

## ■ Requirements analysis

- Analysis of USN application models and scenarios;
- Analysis of service requirements and functional capability requirements; and
- Analysis of further development and relevant standardization items

## ■ Non-IP sensor networking

- ZigBee protocol stack
- TinyOS-based sensor network
- Proprietary sensor networking solutions

## ■ IP sensor networking

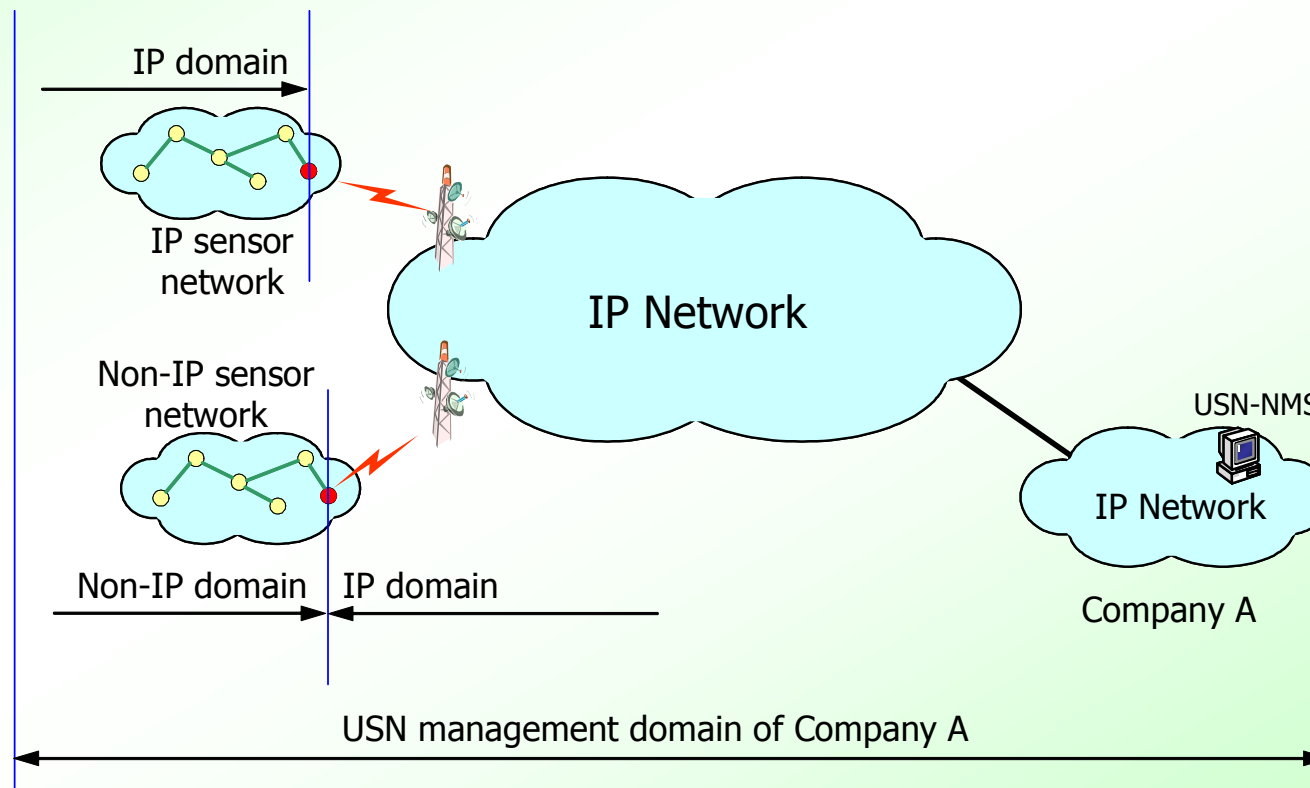

- Tiny TCP/IP networking stack
- IETF 6LoWPAN

- Inter-networking between:
  - Non-IP sensor network and IP network
  - IPv4 or IPv6 sensor network and IPv4 or IPv6 network
- Mobility support
  - Intra-WPAN mobility
  - Inter-WPAN mobility
  - WPAN mobility
- Energy-saving routing protocol
- Energy-saving communication protocols
  - TCP/IP protocol family didn't care for energy saving.
  - Energy-saving communication protocols need to be developed.

## ■ USN management

- Commissioning
- Network management

## ■ Security

- Telco-provided security capabilities could be a good solution for sensor node protection and other security requirements.

## ■ Directory service

- Sensor node identification for management
- Public USN information service

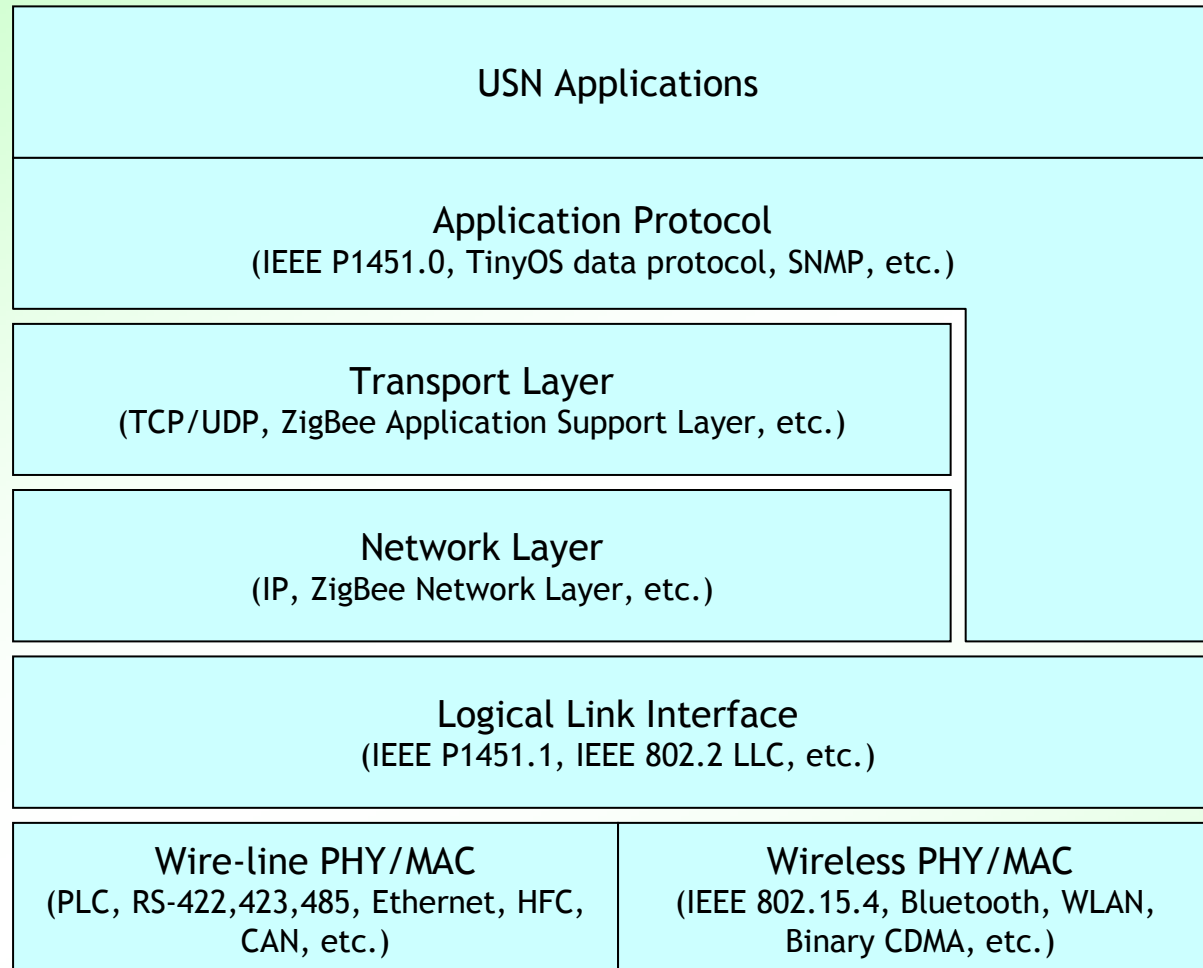

## ■ Middleware functions

- Context awareness support

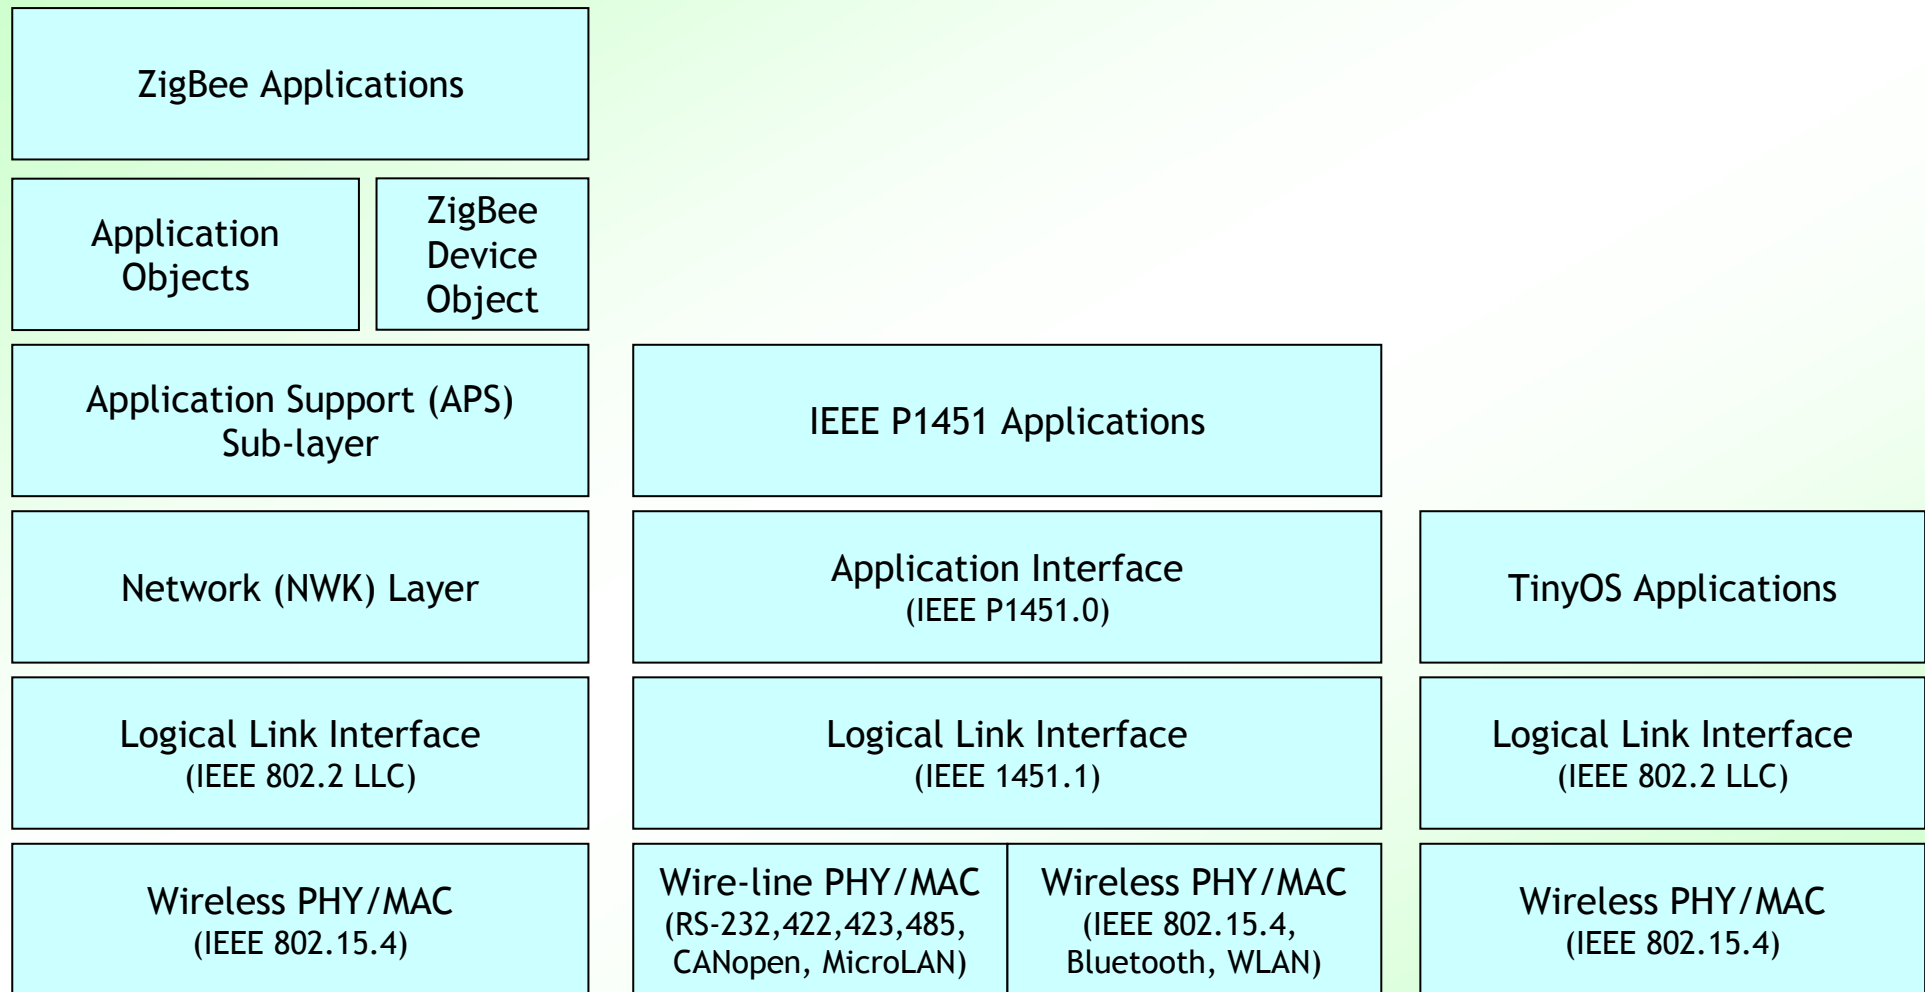

## ■ Open service environment

- value-added information resources should be integrated with other information contents or services.

# USN Technology Layer Model

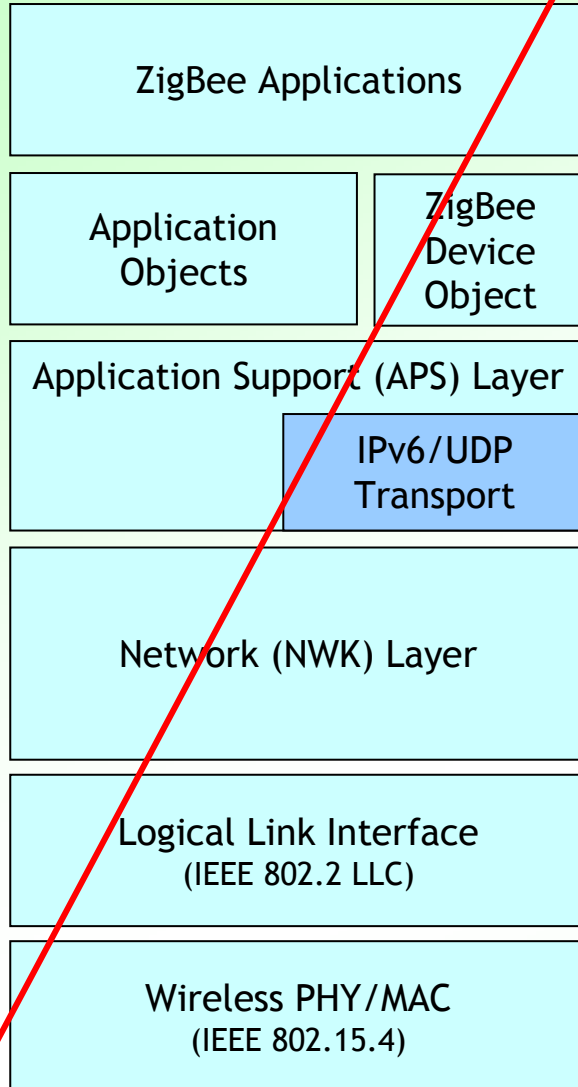

# Non-IP USN Networking Solutions

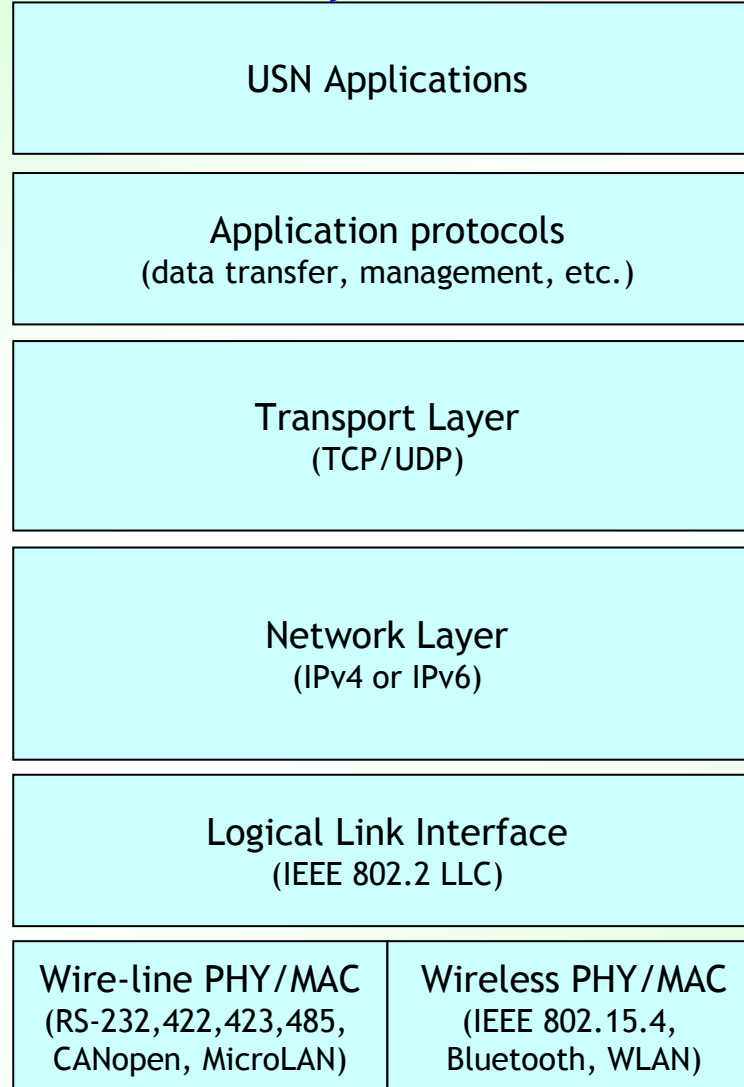

# IP-USN Networking Solutions

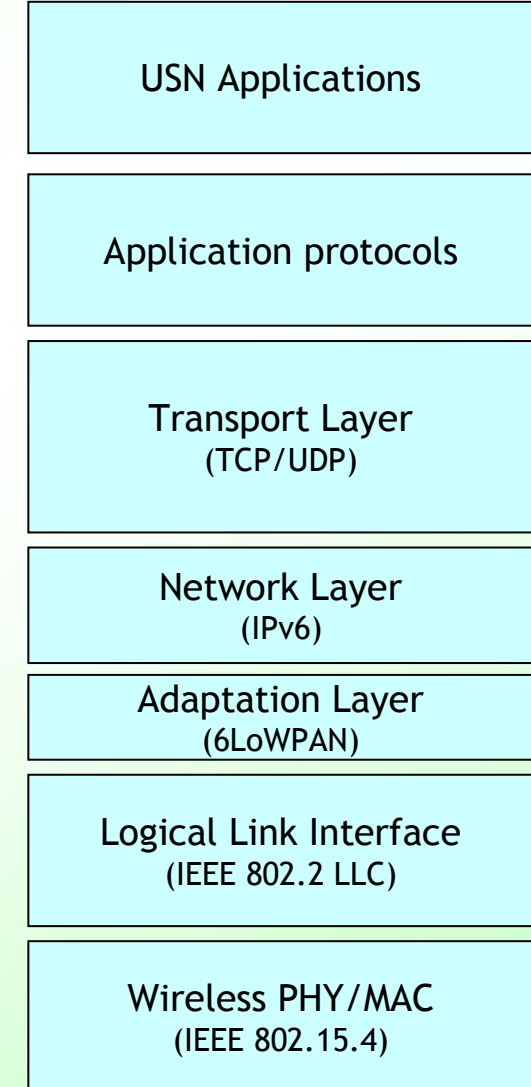

## ZigBee-IPv6

## Tiny TCP/IP

## 6LoWPAN

- USN is information service infrastructure to cover low layers to higher layers.
- USN has various problem domains to be tackled.
- USN service requirements cause new challenging functionality requirements.
- So, future Internet architecture should care for USN.

# Q/A
